The present invention is related to a method and apparatus for power line load equalization. The method and apparatus are related to the automatic power load equalization system disclosed in U.S. Pat. No. 5,752,108 issued to Feldstein and Dinkhauser,

and U.S. Pat. No. 6,894,473 issued to Feldstein and Dinkhauser, and incorporated herein by reference. As indicated in the above references, power distribution networks include multiple pieces of equipment that are connected to the power lines. Often, the electrical loads are not evenly distributed across the power distribution

network. For example, in a power distribution network that operates at 230 volts, the loads may be 60% residential, 20% commercial, and 20% industrial. As a result, this is a typical variation in the type and amount of power used by customers served by the power distribution network. In a power distribution network, the loads may be presented to

the power lines in a wide variety of ways, including single-line, single-branch, and multibranched configurations. A single-line system is a single-branch line that is not connected to any loads. A multibranched system includes any number of branch lines that are connected to the load. A single-line system and a multi-branched system

may be present at a single location. In general, electrical loads do not always follow the path of shortest distance between a power source and a load. For example, a load may be connected to a power source at or near the end of a branch line. The load may draw more current than the source can supply, causing voltage to decrease, or

“droop,” while still maintaining the same overall AC voltage. This problem is sometimes known as power droop. Consequently, the power distribution network may have, at times, excess power near the end of a branch line and a shortage of power near the beginning of the branch line. Traditionally, before being powered, the branch

line is energized with power. When the load becomes attached to the line, the loads draws power from the source. This traditionally may occur by, for example, attaching a load to a service panel, turning the main service breakers on, or attaching a load to a branch line on a dedicated bus. Once connected, the system will continue to

deliver power to the load.
As a result, if the branch
line has a shortage of
