dfscdmatooleddrar40 You're looking in the wrong direction. In general, it is better not to deal with them. Except that they don't pay, they don't work, and I just buy from them. Here, for example, is how we are working with these guys now. I have 8 servers in my order. I do not pay them right away, I give them time to think about how I can make everything fit me. They send me a list of servers that match. As a result, I choose what I like from this list.

Library? I am creating a workflow which would require to call a web service and wait until the result gets back on a page (wait state). The problem is that I am using a library with many pages (I don't know exactly how many) which contents may change from time to time. I don't want to have a loop that goes through each page of the library and every time check if the result of the last call is null because it will be confusing and very time consuming if for some pages the result of the last call is something I don't want (the library has both "active" and "archive" pages). So, is there a way to know which is the current page so I can put a wait state on the web service call only on that page and continue working on

the other pages? A: You could use the \$ctx.currentItem property: You could also check for the URL in your c# code using

```
var currentItem = _clientContext.Web.GetListItem(context.ListId);  
var currentItemUrl = currentItem.C6A93DA74D
```
